draw

Capital calls where each LP sees only its own notice.

DRAW runs a fund’s capital call on Canton. Each LP gets a private notice and pays it in a Canton token, and the money counts only once the ledger confirms it.

Live on Canton DevNet: drawcalls.xyz

A capital call is often a notice, a wire and a spreadsheet.

A notice is just an email, so fake ones work. And someone matches wires to LPs by hand before the fund knows what it can invest.

Our hypothesis, drawn from public sources.

> “A wide range of scams using fake capital call or drawdown notices, falsified invoices or fraudulent loan repayment instructions has been detected.”

Luxembourg Financial Intelligence Unit
Trend alert, November 2025

Built for the person who runs the call.

The operations lead at an emerging fund manager, or the administrator who runs calls for several of them.

The question DRAW answers

How much of this call is deployable right now, and what's still unresolved?

Issue once. Each LP pays its own notice.

1

Issue

The fund issues one call. Each LP gets a private notice.

2

Pay

The LP locks the exact amount in a Canton token allocation.

3

Settle

One transaction checks the amount and moves the coin to the fund.

4

Verify

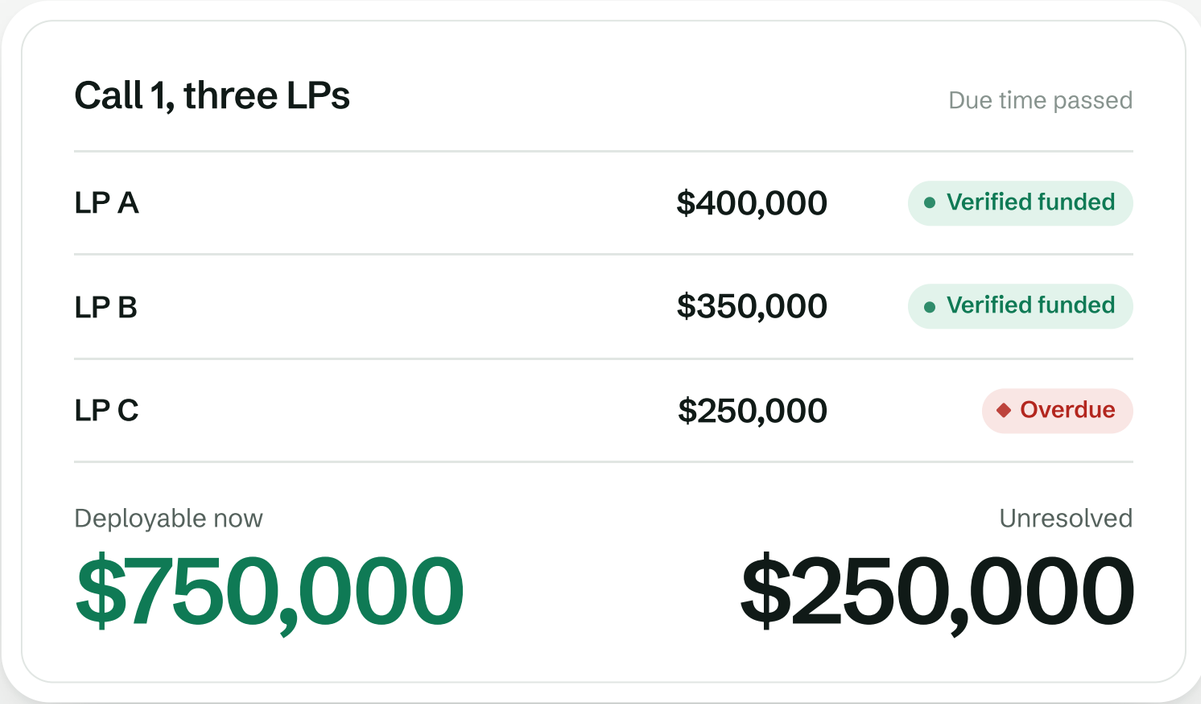

A separate read-back finds the settlement on the ledger. Only then is the notice verified funded and the money deployable.

DevNet

It runs on Canton DevNet today.

Two LPs paid and one didn’t. The fund sees exactly what it can deploy and what’s still open.

Scripted DevNet run, each party signing with its own key, all five keys on one machine. Test Canton Coin, scenario dollars.

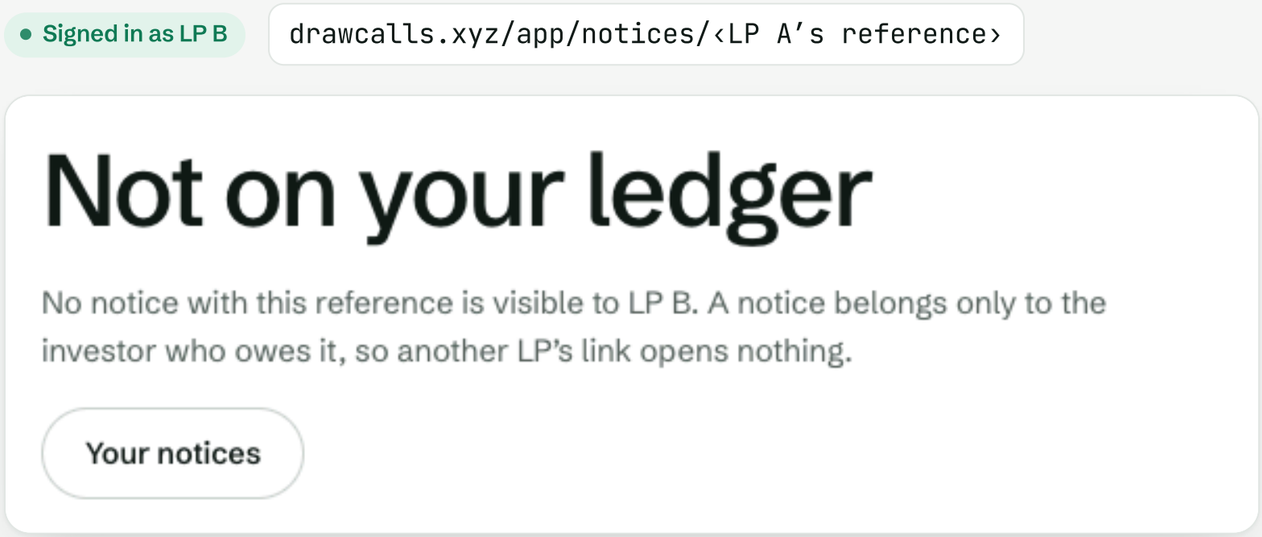

DevNet

LP B opens LP A’s notice. The ledger returns nothing.

A notice exists only if the fund issued it on the ledger, and only its LP can read it. Nothing comes back for anyone else.

On DevNet one backend login reads for every demo seat. Separate logins per LP were tested on LocalNet.

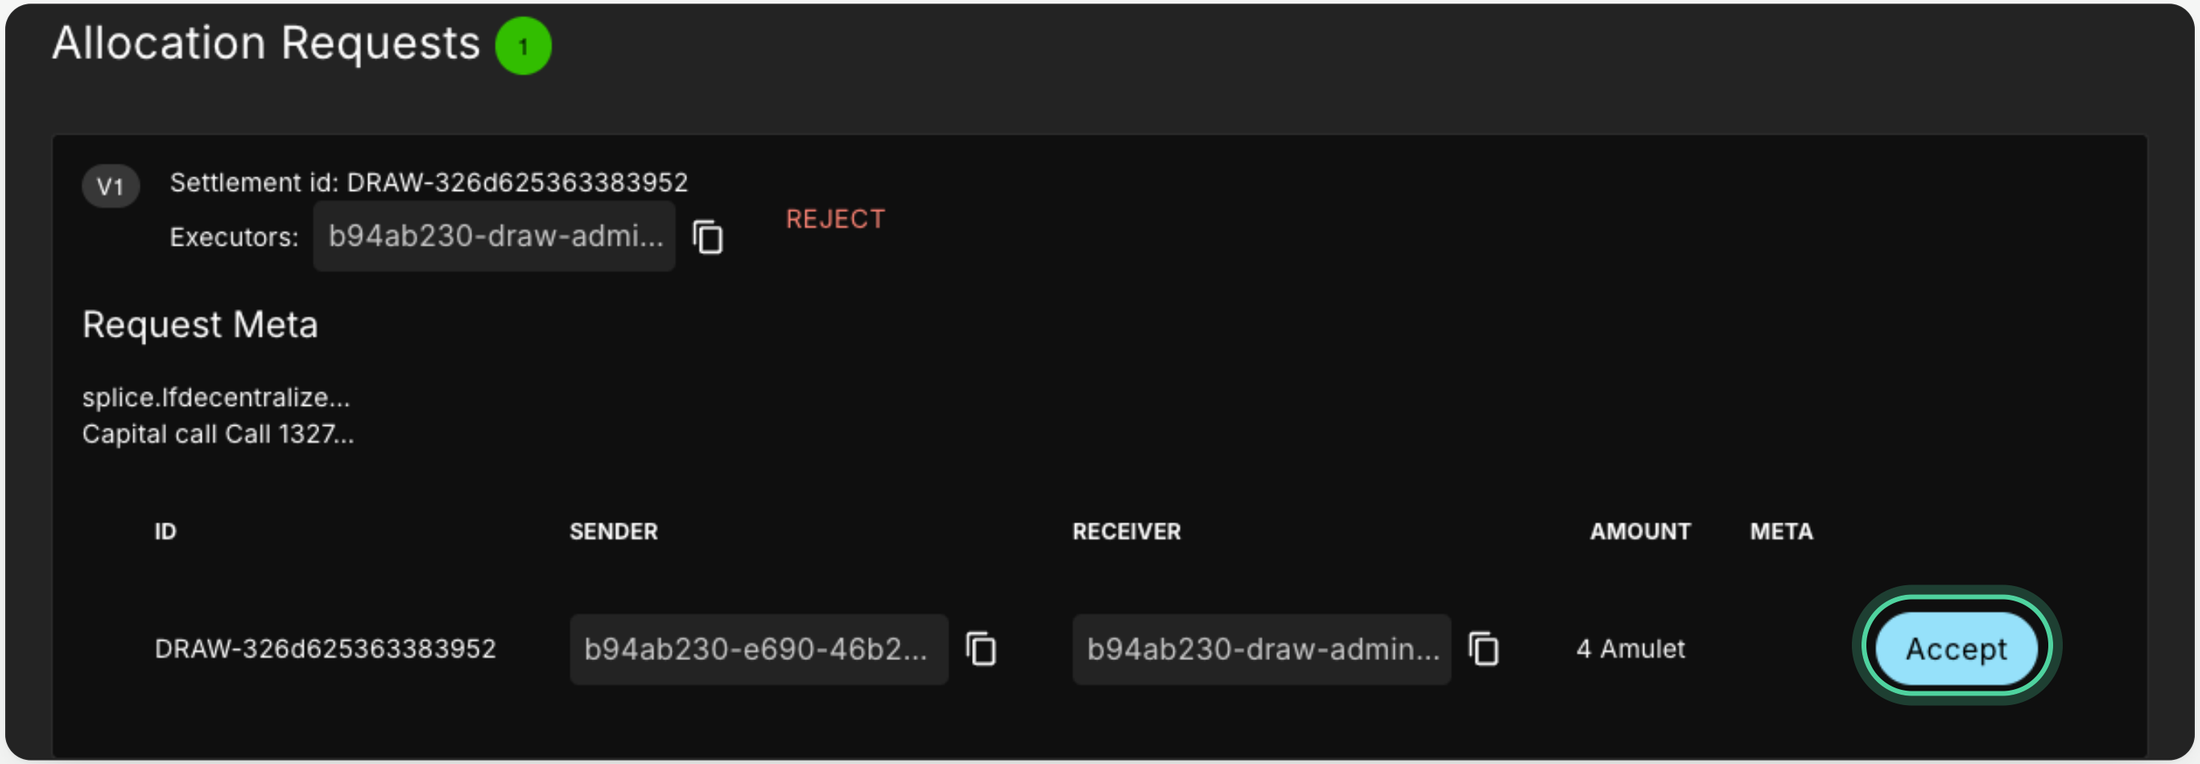

DevNet

An LP pays from its own Canton wallet.

The call shows up in the LP’s Canton Coin wallet as a payment request. The LP presses Accept.

9 of 9 steps on drawcalls.xyz, from sign-in to verified funded. We signed in as the LP with our own HackCanton login. On 2026-10-09 a person outside the team paid as an LP too.

Amulet is Canton Coin’s token name.

Same call, same five attacks. A database let 4 through. DRAW let none through.

Database with a paid flag

4 of 5 got through

An unpaid LP marked funded, another LP's notice read, a payment reused, a row counted as money.

DRAW on Canton

0 of 5 got through

The ledger refused every one.

Each notice is visible only to the fund and that LP, and the coin moves in the same atomic transaction that updates the notice.

LocalNet. The database attacker had write access, as an operator or a compromised app server would.

Every number comes from a scripted run.

DevNet

83/83

lifecycle checks, every party signing with its own key

LocalNet

76/76

custody checks, every party signing with its own key

LocalNet

100/100

generated calls with no false funding and no leaks

Daml tests

15/15

deliberately broken guards caught

Test Canton Coin and scenario dollars.
On DevNet all five keys sat on one machine.

On the live site, DRAW's login signs for the demo LPs.
Not yet run with USDCx.

Start with the administrators who run the calls.

First

Administrators

One administrator runs calls for several emerging managers, so one relationship reaches several funds.

Next

Shadow one real call

DRAW runs next to the fund’s spreadsheet until the call closes. No money moves.

Then

First paid calls on TestNet with USDCx

A dollar settlement asset whose registry lists the same allocation API DRAW uses today. Not yet run.

Hypothesis Per-fund pricing for managers, per-call for administrators. No interviews held yet.

Help us run one real call.

1. An introduction to a fund ops lead or administrator who’d shadow one call.
2. Help moving from test coin to a real dollar token on Canton’s TestNet.
